Power Transformer Design. The skeleton of the power transformer is designed with metal which is laminated by sheets. It is fixed into either a core type or shell type. The skeletons of the transformer are wound and connected using conductors to make three 1-phase or one 3-phase transformer.

without a change in frequency. It contains primary and secondary winding. The primary winding is connected to the main supply and secondary to the required circuit.

The two most common and basic designs of transformer construction are the Closed-core Transformer and the Shell-core Transformer. In the "closed-core" type (core form) transformer, the primary and secondary windings are wound outside and surround the core ring.

~~Transformer Construction and Transformer Core Design~~

Design of core Rectangular core: It is used for core type distribution transformer and small power transformer for moderate and low voltages and shell type transformers. In core type transformer the ratio of depth to width of core varies between 1.4 to 2. In shell type transformer width of central limb is 2 to 3 times the depth of core.

~~DESIGN OF TRANSFORMER~~

Optimum Design of Cross-Section of Transformer Core The maximum flux density of CRGO steel is about 1.9 Tesla. Means the steel becomes saturated at the flux density 1.9 Tesla. One important criteria for the design of transformer core, is that, it must not be saturated during the transformer's normal operation mode.

Three phase core type transformer . Rating of the transformer in kVA = $V_{111} \times 10^{-3} = E_{111} \times 10^{-3} = 3 \times 4.44 \times m f T \times I_{11} \times 10^{-3}$ (1) Note: Since there are two windows, it is sufficient to design one of the two windows, as both the windows are symmetrical. Since each leg carries the LV & HV windings of one phase, each window carry the LV & HV windings of two phases

~~Output Equations and Main Dimensions Design of Transformers~~

The efficiency of a transformer is reflected in power (wattage) loss between the primary (input) and secondary (output) windings. Then the resulting efficiency of a transformer is equal to the ratio of the power output of the secondary winding, PS to the power input of the primary winding, PP and is therefore high.

~~Transformer Basics and Transformer Principles~~

As, we are going to design a practical transformer so we must consider the core available in market. The standard Bobbins available in market practically is 1×1 , 1.25×1.5 , 1.5×1.5 and so on. We took nearest core area available to our calculation. We took bobbin of 2.25 inch^2 (1.5×1.5) or 0.00145161 m^2 .

Construction of a Transformer The transformer mainly consists of the Magnetic circuit, electric circuit, dielectric circuit, tanks, and accessories. The main elements of the transformer are the primary and secondary windings and the steel core. The core of the transformer is made up of silicon steel in order to provide a continuous magnetic path.

~~Construction of a Transformer Circuit Globe~~

A transformer is a passive electrical device that transfers electrical energy from one electrical circuit to another, or multiple circuits. A varying current in any one coil of the transformer produces a varying magnetic flux in the transformer's core, which induces a varying

~~What is a Step Down Transformer? | Electronic Design~~

A transformer that is designed to generate an output voltage that is higher than the input voltage is called a step-up transformer. An important application of step-up transformers is greatly increasing the voltage generated by a power plant so that the electrical energy can be efficiently transferred over long distances.
