Chapters 5, 6, and 7 concentrate on the three major decomposition methods: Cholesky, QR, and LU. Of course, the goal is to develop methods for sparse linear systems in C. Chapter 7 is devoted to fill-reducing orderings, which are used to minimize the work done by the previous algorithms.

Most of the current techniques for the direct solution of linear equations are based on supernodal or multifrontal approaches. An important feature of these methods is that arithmetic is performed on dense submatrices and Level 2 and Level 3 BLAS (matrix- vector and matrix-matrix kernels) can be used.

Sparse Direct Methods 5 focuses on right-looking Gaussian elimination, and in two related papers (1977a, 1977b), also considers graphs, the block triangular form, Cholesky factorization, and least-squares problems. Du (1977b) gave an extensive survey of sparse matrix methods and their applications with over 600 references.

References for direct methods for sparse linear systems

All sparse linear solvers belong to one of two families: iterative (also called matrix-free) or direct algorithms. Iterative solvers access system matrix A only by evaluating its products $A \cdot x$ (or $A' \cdot x$ with trial vectors x provided by the solver. Direct solvers work with explicit representation of A and perform some sparse triangular factorization (Cholesky or LU with pivoting), followed by solution of sparse triangular system.

An oblique projection method is adapted to solve large, sparse, unstructured systems of linear equations. This row-projection technique is a direct method which can be interpreted as an oblique Kaczmarz-type algorithm, and is also related to other standard solution methods.

Sparse direct solvers are recommended for large 3D finite element models such as multi-story buildings, shell structures, and solid structures. The sparse method involves solving the linear equation system $K * x = b$ or the equation system of eigenvalue problems $K - B = 0$. The direct sparse solvers (SPDS) are efficient computational techniques based on decomposition of the matrix $K = L * U$ with a considerably less number of matrix elements different from zero.
